Feel free to use these slides verbatim, or to modify them to fit your own needs. If you make use of a significant portion of these slides in your own lecture, please include this message, or a link to our web site: <http://www.mmds.org>

Advertising on the Web

CS246: Mining Massive Datasets

Jure Leskovec, Stanford University

Mina Ghashami, Amazon

<http://cs246.stanford.edu>

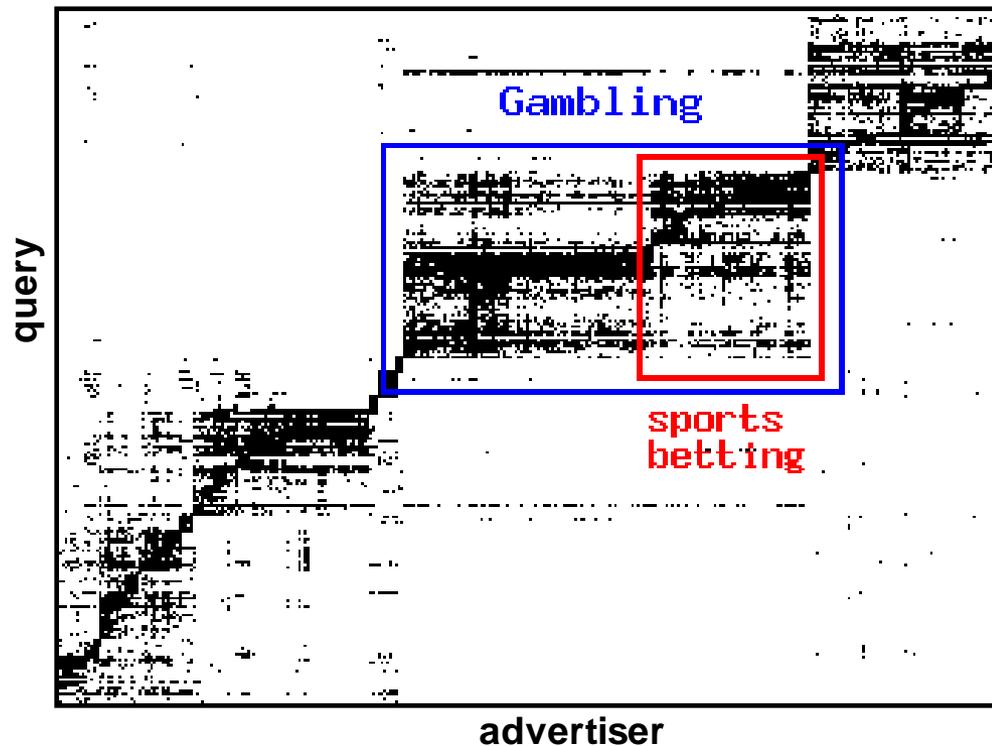

Online Algorithms

- **Classic model of algorithms**
 - You get to see the entire input, then compute some function of it
 - In this context, “**offline** algorithm”
- **Online Algorithms**
 - You get to see the input one piece at a time, and need to make irrevocable decisions along the way
 - **Similar to the data stream model**

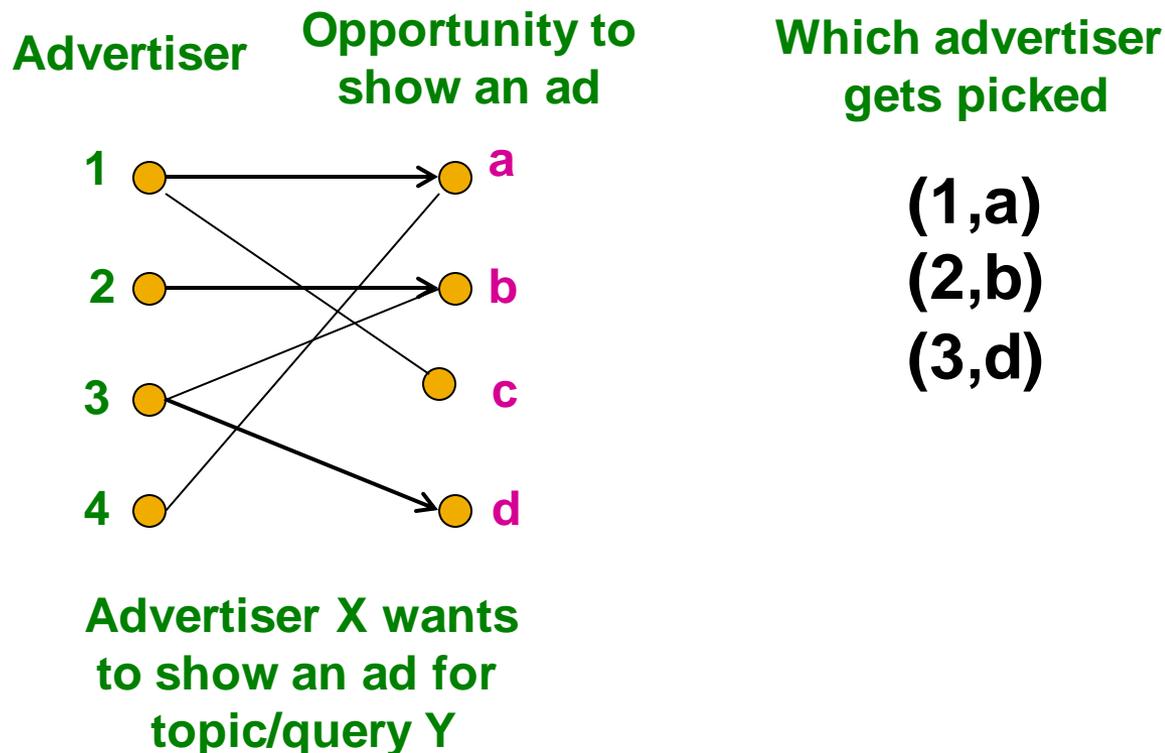

Sponsored Search: Ads

- Query-to-advertiser graph:

[Andersen, Lang: Communities from seed sets, 2006]

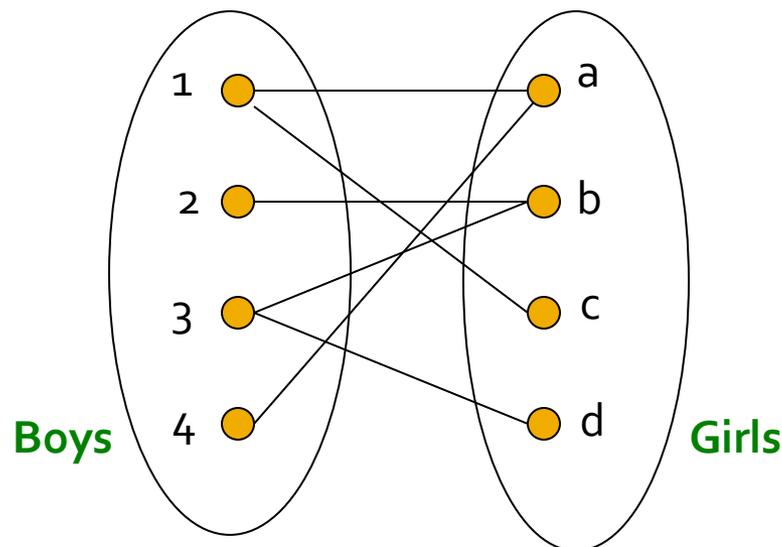

Graph Matching for Advertising

This is an online problem: We have to make decisions as queries/topics show up. We do not know what topics will show up in the future.

Online Bipartite Matching

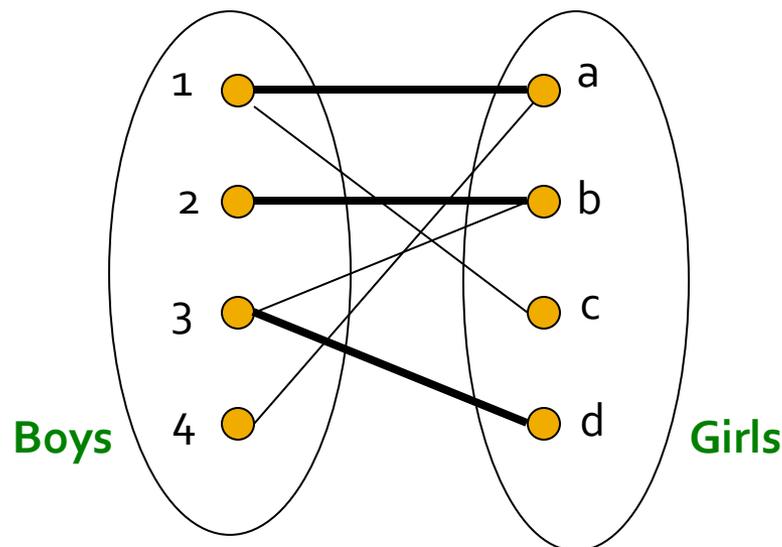

Example: Bipartite Matching

Nodes: Boys and Girls; Links: Preferences
Goal: Match boys to girls so that the most preferences are satisfied

Note: edges are only preferences with no weight or order.

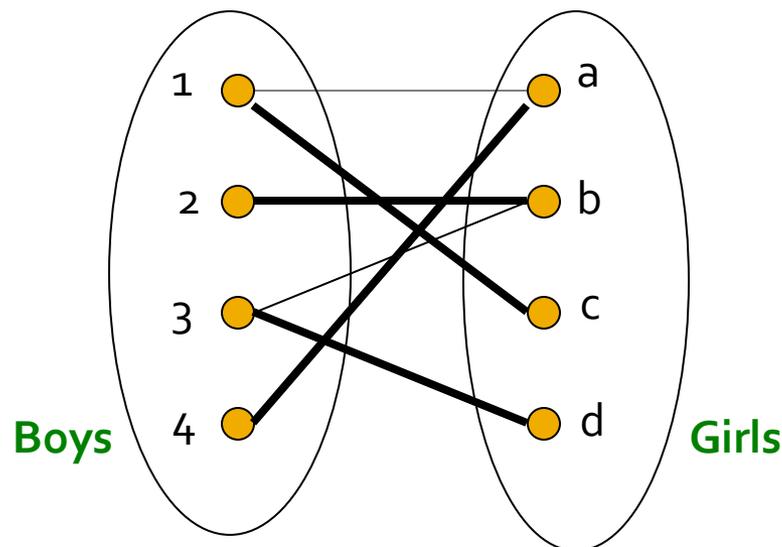

Example: Bipartite Matching

$M = \{(1,a), (2,b), (3,d)\}$ is a **matching**
Cardinality of matching = $|M| = 3$

Matching means that we are not using any vertex twice

Example: Bipartite Matching

$M = \{(1,c), (2,b), (3,d), (4,a)\}$ is a
perfect matching

Perfect matching ... all vertices of the graph are matched

Maximum matching ... matching that contains the largest possible number of matches

Matching Algorithm

- **Problem:** Find a maximum matching for a given bipartite graph
 - A perfect one if it exists
- There is a polynomial-time offline algorithm based on augmenting paths (Hopcroft & Karp 1973, see http://en.wikipedia.org/wiki/Hopcroft-Karp_algorithm)
- **But what if we do not know the entire graph upfront?**

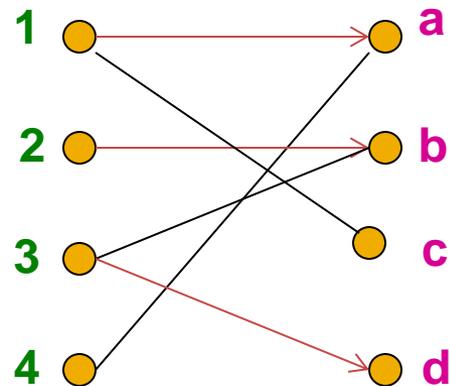

Online Graph Matching Problem

- Initially, we are given the set **boys**
- In each **round**, **one girl's choices are revealed**
 - That is, the girl's **edges** are revealed
- **At that time, we have to decide to either:**
 - Pair the **girl** with a **boy**
 - Do not pair the **girl** with any **boy**
- **Example of application:**

Assigning tasks to servers

Note: Matching means that we are not using any girl or boy twice

Online Graph Matching: Example

(1,a)

(2,b)

(3,d)

Greedy Algorithm

- **Greedy algorithm for the online graph matching problem:**
 - Pair the new girl with **any** eligible boy
 - If there is none, do not pair the girl
- **How good is the algorithm?**

Competitive Ratio

- For input I , suppose greedy produces matching M_{greedy} while an optimal matching is M_{opt}

Competitive ratio =

$$\min_{\text{all possible inputs } I} (|M_{greedy}| / |M_{opt}|)$$

(what is greedy's worst performance over all possible inputs I)

Analyzing the Greedy Algorithm

- Consider a case: $M_{greedy} \neq M_{opt}$
- Consider the set G of girls matched in M_{opt} but not in M_{greedy}

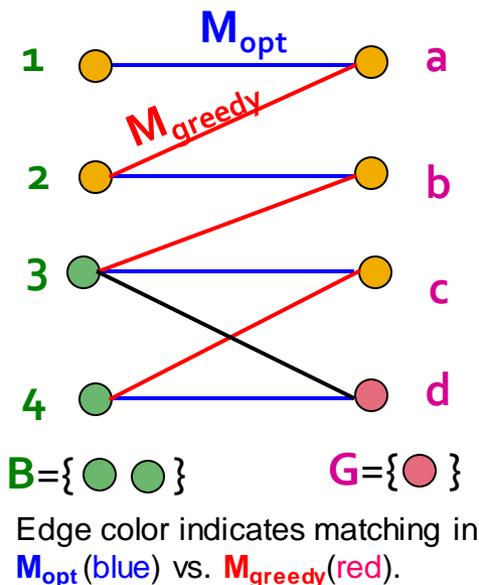

- (1) By definition of G :

$$|M_{opt}| \leq |M_{greedy}| + |G|$$

- (2) Define set B of boys linked to girls in G

- Notice boys in B are already matched in M_{greedy} . Why?
 - If there would exist such non-matched (by M_{greedy}) boy adjacent to a non-matched girl then greedy would have matched them

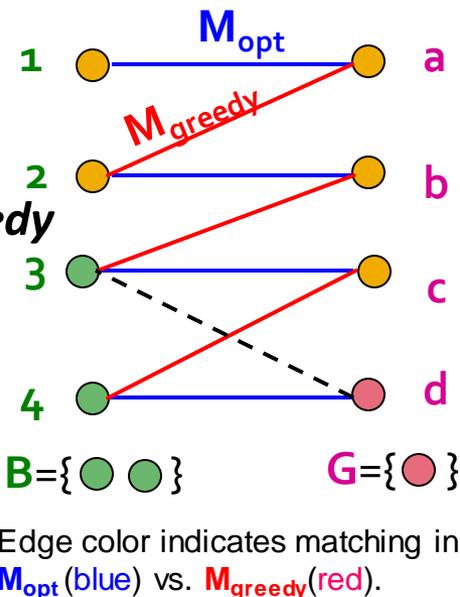

$$\text{So: } |M_{greedy}| \geq |B|$$

Analyzing the Greedy Algorithm

■ Summary so far:

- Girls G matched in M_{opt} but not in M_{greedy}
- Boys B adjacent to girls in G
- (1) $|M_{opt}| \leq |M_{greedy}| + |G|$
- (2) $|M_{greedy}| \geq |B|$

- Optimal matches all girls in G to (some) boys in B
 - (3) $|G| \leq |B|$
- Combining (2) and (3):
 - (4) $|G| \leq |B| \leq |M_{greedy}|$

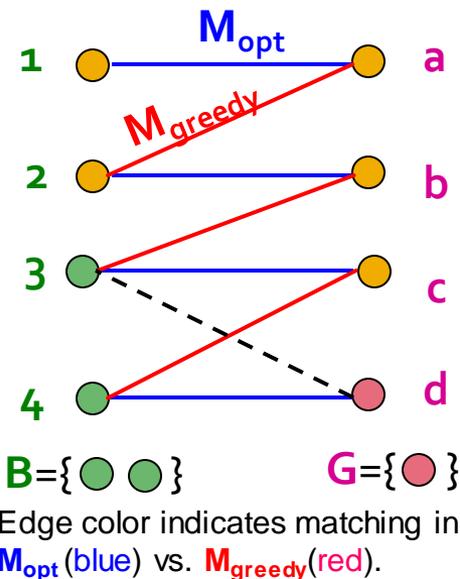

Analyzing the Greedy Algorithm

- So we have:

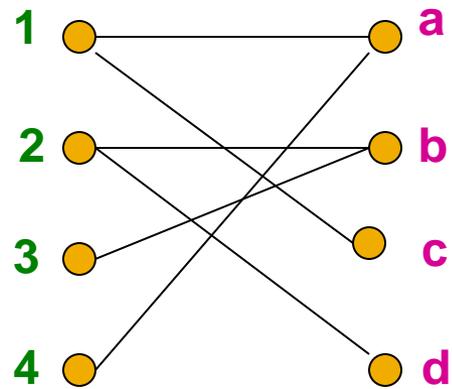

- (1) $|M_{opt}| \leq |M_{greedy}| + |G|$
- (4) $|G| \leq |B| \leq |M_{greedy}|$

- Combining (1) and (4):

- Worst case is when $|G| = |B| = |M_{greedy}|$
- $|M_{opt}| \leq |M_{greedy}| + |M_{greedy}|$
- Then $|M_{greedy}| / |M_{opt}| \geq 1/2$

Worst-case Scenario

(1,a)

(2,b)

Web Advertising

History of Web Advertising

■ **Banner ads (1995-2001)**

- Initial form of web advertising
- Popular websites charged \$X for every 1,000 “impressions” of the ad
 - Called “**CPM**” rate (Cost per thousand impressions)
 - Modeled similar to TV, magazine ads
- From **untargeted** to **demographically targeted**
- **Low click-through rates**
 - Low ROI for advertisers

The screenshot shows the homepage of The New York Times. At the top, there are navigation links for 'MOST POPULAR', 'Edition: U.S. / Global', and 'Subscribe: Home'. The main headline is 'U.S. Sergeant Is Said to Kill 16 Civilians in Afghanistan'. Below the headline, there are several smaller articles and a 'NEWS ANALYSIS' section. On the right side, there is a 'MARKETS' section and a 'GET QUOTES' link. At the bottom right, there is a large green banner for Audible.com with the text 'HEAR GREAT BOOKS PERFORMED BY HOLLYWOOD'S FINEST GET ONE OF THESE BOOKS FREE'. The banner also includes the Audible logo and a 'GO NOW' button. There are several red boxes highlighting specific elements: a box around the top left navigation area, a box around the 'NO DIRECT' button, a box around the 'SHOP NOW AT MARCJACOBS.COM' button, and a box around the Audible.com banner.

CPM...cost per mille
Mille...thousand in Latin

Performance-based Advertising

- **Introduced by Overture around 2000**
 - Advertisers **bid on search keywords**
 - When someone searches for that keyword, the **highest bidder's ad is shown**
 - Advertiser is charged only if the ad is clicked on
- Similar model adopted by Google with some changes around 2002
 - Called **Adwords**

Ads vs. Search Results

Web

Results 1 - 10 of about 2,230,000 for **geico**. (0.04 sec)

Web 2.0

- **Performance-based advertising works!**
 - Multi-billion-dollar industry
- **Interesting problem:**
Which ads to show for a given query?
 - (Today's lecture)
- **If I am an advertiser, which search terms should I bid on and how much should I bid?**
 - (Not focus of today's lecture)

AdWords Problem

- A stream of queries arrives at the search engine: q_1, q_2, \dots
- Several advertisers bid on each query
- When query q_i arrives, search engine must pick a subset of advertisers to show their ads
- **Goal: Maximize search engine's revenues**
 - **Simple solution:** Instead of raw bids, use the “expected revenue per click” (i.e., Bid*CTR)
- **Clearly we need an online algorithm!**

The Adwords Innovation

Advertiser	Bid	CTR	Bid * CTR
A	\$1.00	1%	1 cent
B	\$0.75	2%	1.5 cents
C	\$0.50	2.5%	1.25 cents

Click through
rate

Expected
revenue

The Adwords Innovation

Advertiser	Bid	CTR	Bid * CTR
B	\$0.75	2%	1.5 cents
C	\$0.50	2.5%	1.25 cents
A	\$1.00	1%	1 cent

Instead of sorting advertisers by bid, sort by expected revenue

Limitations of Simple Algorithm

Instead of sorting advertisers by bid, sort by expected revenue

Advertiser	Bid	CTR	Bid * CTR
B	\$0.75	2%	1.5 cents
C	\$0.50	2.5%	1.25 cents
A	\$1.00	1%	1 cent

Challenges:

- CTR of an ad is unknown
- Advertisers have limited budgets and bid on multiple queries

Complications: Budget

- **Two complications:**

- **Budget**
- **CTR of an ad is unknown**

1) Budget: Each advertiser has a limited budget

- **Search engine guarantees that the advertiser will not be charged more than their daily budget**

Complications: CTR

- **2) CTR (Click-Through Rate): Each ad-query pair has a different likelihood of being clicked**
 - **Advertiser 1** bids \$2 on query A, click probability = 0.1
 - **Advertiser 2** bids \$1 on query B, click probability = 0.5
- **CTR** is predicted or measured historically
 - Averaged over a time period
- **Some complications we will not cover:**
 - **1) CTR is position dependent:**
 - Ad #1 is clicked more than Ad #2

Complications: CTR

- **Some complications we will cover (next lecture):**

- **2) Exploration vs. exploitation**

Exploit: Should we keep showing an ad for which we have good estimates of click-through rate?

or

Explore: Shall we show a brand new ad to get a better sense of its click-through rate?

Online Algorithms

The BALANCE Algorithm

Adwords Problem

■ Given:

- 1. A set of bids by advertisers for search queries
- 2. A click-through rate for each advertiser-query pair
- 3. A budget for each advertiser (say for 1 month)
- 4. A limit on the number of ads to be displayed with each search query

■ Respond to each search query with a set of advertisers such that:

- 1. The size of the set is no larger than the limit on the number of ads per query
- 2. Each advertiser has bid on the search query
- 3. Each advertiser has enough budget left to pay for the ad if it is clicked upon

Greedy Algorithm

- **Our setting: Simplified environment**
 - There is **1** ad shown for each query
 - All advertisers have the same budget **B**
 - All ads are equally likely to be clicked
 - Bid value of each ad is the same (**$=\$1$**)
- **Simplest algorithm is greedy:**
 - For a query pick any advertiser who has bid **1** for that query
 - **Competitive ratio of greedy is $1/2$**

Bad Scenario for Greedy

- **Two advertisers A and B**
 - A bids on query x , B bids on x and y
 - Both have budgets of \$4
- **Query stream: $x x x x y y y y$**
 - Worst case greedy choice: $B B B B _ _ _ _$
 - Optimal: $A A A A B B B B$
 - **Competitive ratio = $\frac{1}{2}$**
- **This is the worst case!**
 - **Note:** Greedy algorithm is deterministic – it always resolves draws in the same way

BALANCE Algorithm [MSVV]

- **BALANCE** Algorithm by Mehta, Saberi, Vazirani, and Vazirani
 - **For each query, pick the advertiser with the largest unspent budget**
 - Break ties arbitrarily (**but in a deterministic way**)

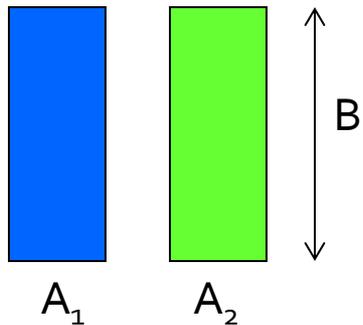

Example: BALANCE

- **Two advertisers A and B**
 - A bids on query x , B bids on x and y
 - Both have budgets of \$4
- **Query stream: $x x x x y y y y$**
- **BALANCE choice: A B A B B B _ _**
 - Optimal: A A A A B B B B
- **In general: For BALANCE on 2 advertisers**
Competitive ratio = $\frac{3}{4}$

Analyzing BALANCE

- **Consider simple case (w.l.o.g.):**
 - 2 advertisers, A_1 and A_2 , each with budget B (≥ 1)
 - Optimal solution exhausts both advertisers' budgets
- **BALANCE must exhaust at least one budget:**
 - **If not, we can allocate more queries**
 - Whenever BALANCE makes a mistake (both advertisers bid on the query), advertiser's unspent budget only decreases
 - Since optimal exhausts both budgets, one will for sure get exhausted
 - Assume BALANCE exhausts A_2 's budget, but allocates x queries fewer than the optimal
 - **So revenue of BALANCE = $2B - x$** (where OPT is $2B$)
 - **Let's work out what x is!**

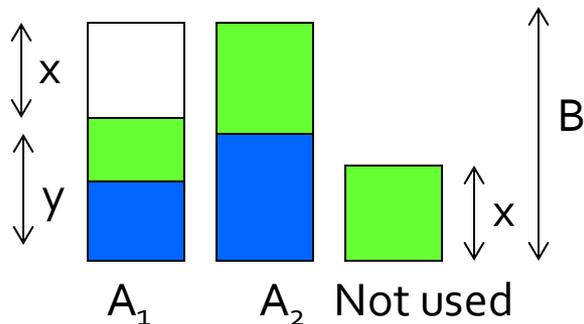

Analyzing Balance

■ Queries allocated to A_1 in optimal solution

■ Queries allocated to A_2 in optimal solution

Opt revenue = $2B$

Balance allocation

Balance revenue = $2B - x = B + y$

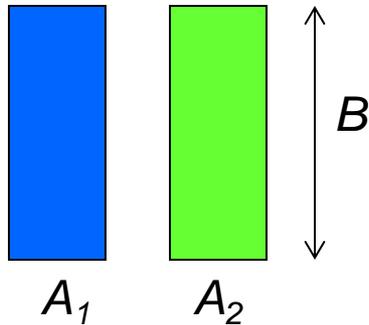

We claim $y \geq x$ (next slide).

Balance revenue is minimum for $x=y=B/2$.

Minimum Balance revenue = $3B/2$.

Competitive Ratio = $3/4$.

Analyzing BALANCE: What's x ?

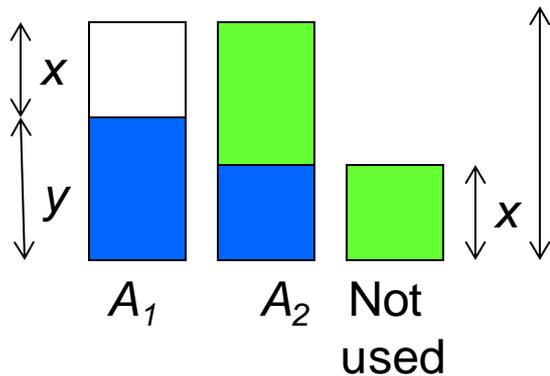

- Queries allocated to A_1 in the optimal solution
- Queries allocated to A_2 in the optimal solution

Optimal revenue = $2B$

Assume Balance gives revenue = $2B - x = B + y$

Assume we exhausted A_2 's budget

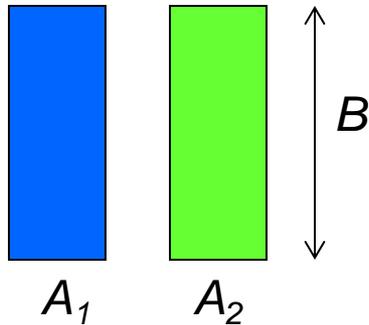

Notice: Unassigned queries should be assigned to A_2 (since if we could assign to A_1 we would since we still have the budget)

Goal: Show we have $y \geq B/2$

Case 1) BALANCE assigns $\geq B/2$ blue queries to A_1 .

Then trivially, $y \geq B/2$

Analyzing BALANCE: What's x ?

- Queries allocated to A_1 in the optimal solution
- Queries allocated to A_2 in the optimal solution

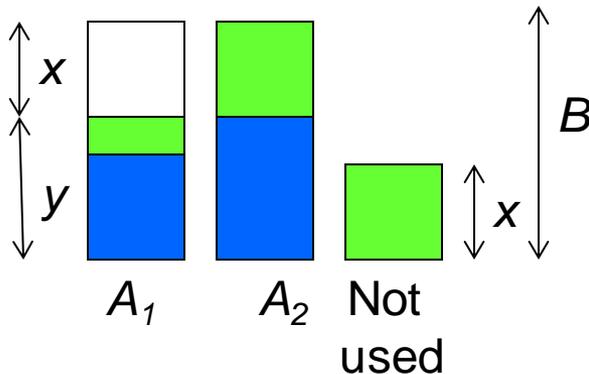

Optimal revenue = $2B$

Assume Balance gives revenue = $2B - x = B + y$

Assume we exhausted A_2 's budget

Unassigned queries should be assigned to A_2
(if we could assign to A_1 we would since we still have the budget)

Goal: Show we have $y \geq B/2$

Balance revenue is minimum for $x = y = B/2$

Minimum Balance revenue = $3B/2$

Competitive Ratio: $BAL/OPT = 3/4$

Case 2) BALANCE assigns $\geq B/2$ blue queries to A_2 .

Consider the last blue query assigned to A_2 .

At that time, A_2 's unspent budget must have been at least as big as A_1 's.

That means at least as many queries have been assigned to A_1 as to A_2 .

At this point, we have already assigned at least $B/2$ queries to A_2 .

So, $x \leq B/2$ and $x + y = B$ then $y > B/2$

BALANCE: General Result

- In the general case, worst competitive ratio of BALANCE is $1 - 1/e = \text{approx. } 0.63$
 - $e = 2.7182$
 - Interestingly, no online algorithm has a better competitive ratio!
- Let's see the worst case example that gives this ratio

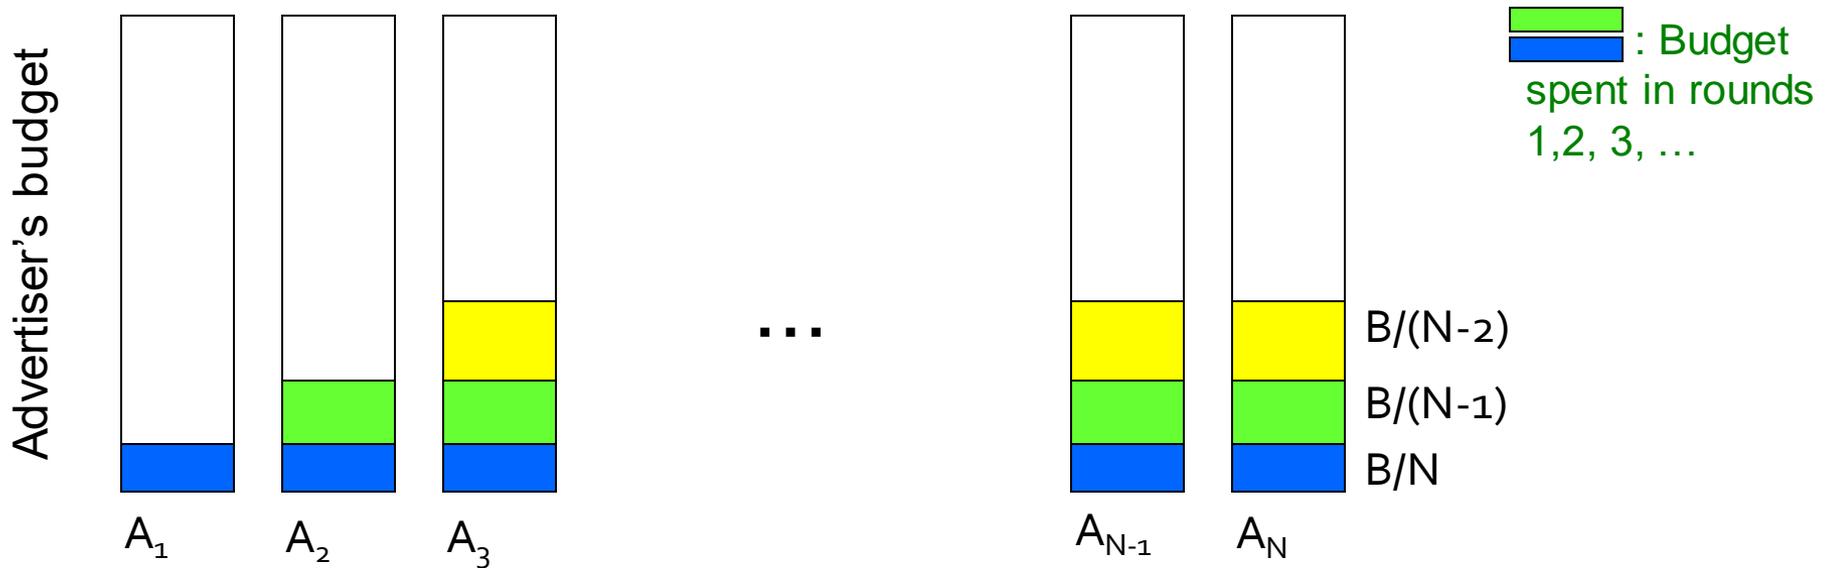

Worst case for BALANCE

- **N advertisers:** A_1, A_2, \dots, A_N
 - Each with budget $B > N$
- **Queries:**
 - $N \cdot B$ queries appear in N rounds of B queries each
- **Bidding:**
 - Round 1 queries: bidders A_1, A_2, \dots, A_N
 - Round 2 queries: bidders A_2, A_3, \dots, A_N
 - Round i queries: bidders A_i, \dots, A_N
- **Optimum allocation:**

Allocate all round i queries to A_i

 - Optimum revenue $N \cdot B$

BALANCE Allocation

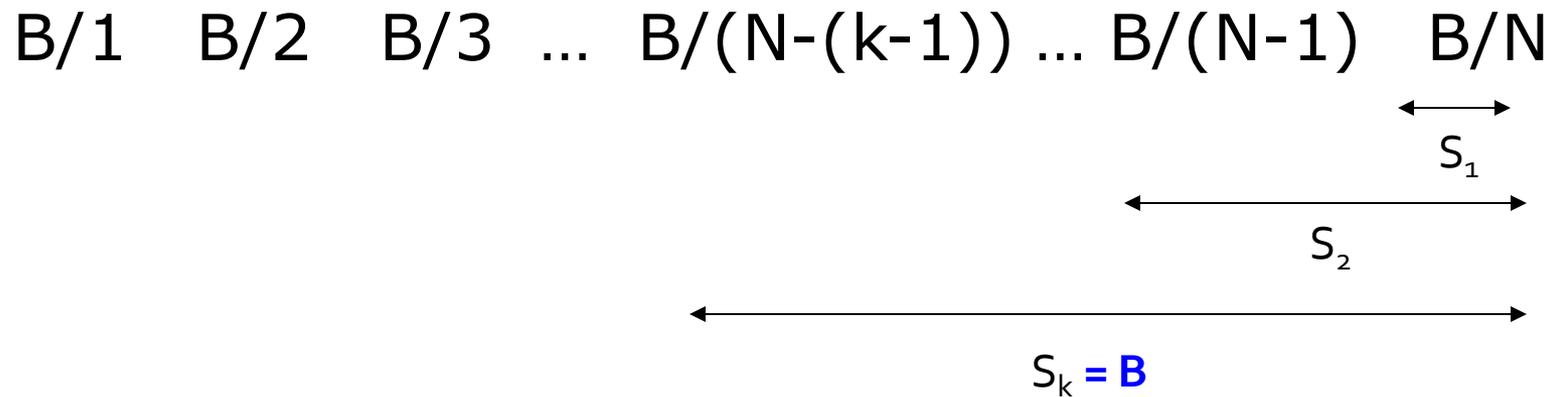

BALANCE assigns each of the queries in round 1 to N advertisers. After k rounds, sum of allocations S_k to each of advertisers

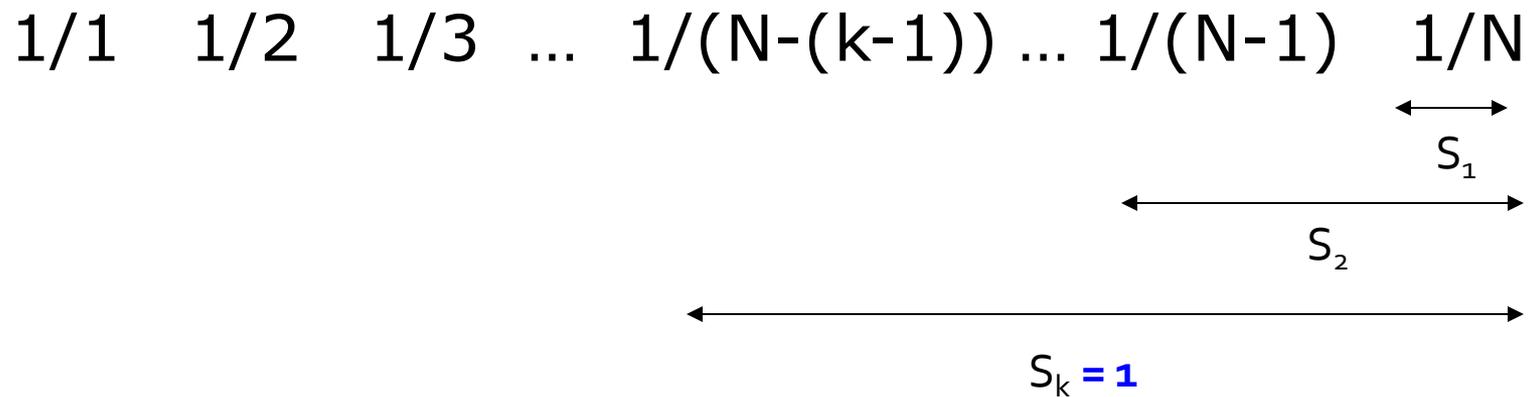

$$A_1, \dots, A_N \text{ is } S_k = S_{k+1} = \dots = S_N = \sum_{i=1}^k \frac{B}{N-(i-1)}$$

If we find the smallest k such that $S_k \geq B$, then after k rounds we cannot allocate any queries to any advertiser

BALANCE: Analysis

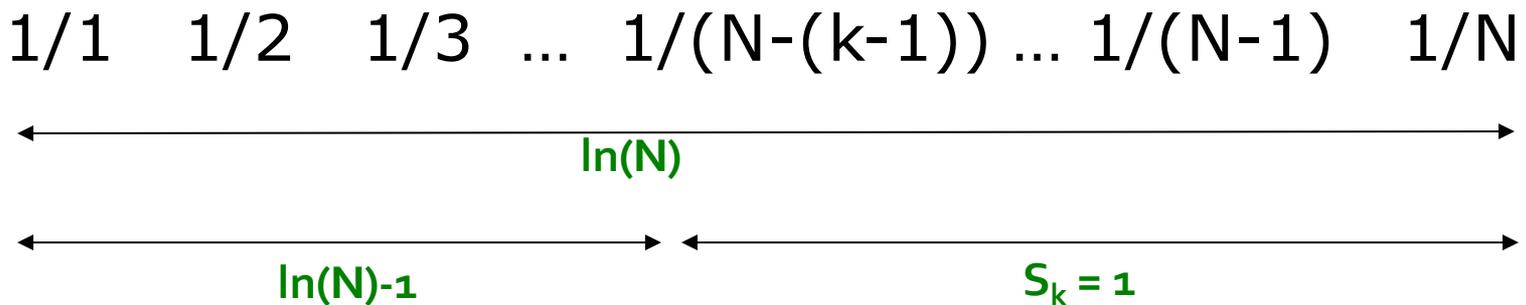

Can divide everything by B:

BALANCE: Analysis

- **Fact:** $H_n = \sum_{i=1}^n 1/i \approx \ln(n)$ for large n
 - Result due to Euler

- $S_k = 1$ implies: $H_{N-k} = \ln(N) - 1 = \ln\left(\frac{N}{e}\right)$
 - We also know: $H_{N-k} = \ln(N - k)$
 - So: $N - k = \frac{N}{e}$
 - Then: $k = N\left(1 - \frac{1}{e}\right)$
- N terms sum to $\ln(N)$.
Last k terms sum to 1.
First $N-k$ terms sum to $\ln(N-k)$ but also to $\ln(N)-1$

BALANCE: Analysis

- So after the first $k=N(1-1/e)$ rounds, we cannot allocate a query to any advertiser
- Revenue = $B \cdot N (1-1/e)$
- Competitive ratio = $1-1/e$
- Note: So far we assumed:
 - All advertisers have the same budget B
 - All advertisers bid 1 for the ad
 - (but each advertiser can bid on any subset of ads)

General Version of the Problem

- **Arbitrary bids and arbitrary budgets!**
- Consider we have 1 query q , advertiser i
 - Bid = x_i
 - Budget = b_i
- **In a general setting BALANCE can be terrible**
 - Consider two advertisers A_1 and A_2
 - $A_1: x_1 = 1, b_1 = 110$
 - $A_2: x_2 = 10, b_2 = 100$
 - Consider we see **10** instances of q
 - BALANCE always selects A_1 and earns **10**
 - Optimal earns **100**

Generalized BALANCE

- **Arbitrary bids:** consider query q , bidder i
 - Bid = x_i
 - Budget = b_i
 - Amount spent so far = m_i
 - Fraction of budget left over $f_i = 1 - m_i/b_i$
 - Define $\psi_i(q) = x_i(1 - e^{-f_i})$
- Allocate query q to bidder i with largest value of $\psi_i(q)$
- **Same competitive ratio $(1 - 1/e) = 0.63$**
